

React.js cheatsheet

Data doesn't have to be difficult.

Move fast, grow big w/ MongoDB
Atlas. Try now.

ads via Carbon

React is a JavaScript library for building user interfaces. This guide targets React v15 to v16.

Components

```
import React from 'react'
import ReactDOM from 'react-dom'
```

```
class Hello extends React.Component {
  render () {
    return <div className='message-box'>
      Hello {this.props.name}
    </div>
  }
}
```

```
const el = document.body
ReactDOM.render(<Hello name='John' />, el)
```

Use the [React.js jsfiddle](#) to start hacking. (or the unofficial [jsbin](#))

Import multiple exports

```
import React, {Component} from 'react'
import ReactDOM from 'react-dom'
```

```
class Hello extends Component {
  ...
}
```

Properties

```
<Video fullscreen={true} autoplay={false} />
```

```
render () {
```

```
  ...  
}
```

Use `this.props` to access properties passed to the component.

See: [Properties](#)

States

```
constructor(props) {  
  super(props)  
  this.state = { username: undefined }  
}
```

```
this.setState({ username: 'rstacruz' })
```

```
render () {
```

```
  ...  
}
```

Use `states (this.state)` to manage dynamic data.

With [Babel](#) you can use [proposal-class-fields](#) and get rid of constructor

```
class Hello extends Component {  
  state = { username: undefined };  
  ...  
}
```

See: [States](#)

Nesting

```

class Info extends Component {
  render () {
    const { avatar, username } = this.props

    return <div>
      <UserAvatar src={avatar} />
      <UserProfile username={username} />
    </div>
  }
}

```

As of React v16.2.0, fragments can be used to return multiple children without adding extra wrapping nodes to the DOM.

```

import React, {
  Component,
  Fragment
} from 'react'

class Info extends Component {
  render () {
    const { avatar, username } = this.props

    return (
      <Fragment>
        <UserAvatar src={avatar} />
        <UserProfile username={username} />
      </Fragment>
    )
  }
}

```

Nest components to separate concerns.

See: [Composing Components](#)

Children

```

<AlertBox>

</AlertBox>

```

```

class AlertBox extends Component {
  render () {
    return <div className='alert-box'>

```

```
    </div>
  }
}
```

Children are passed as the `children` property.

Defaults

Setting default props

```
  color: 'blue'
}
```

See: [defaultProps](#)

Setting default state

```
class Hello extends Component {
  constructor (props) {
    super(props)

  }
}
```

Set the default state in the `constructor()`.

And without constructor using [Babel](#) with [proposal-class-fields](#).

```
class Hello extends Component {

}
```

See: [Setting the default state](#)

Other components

Functional components

```
return <div className='message-box'>
  Hello {name}
</div>
}
```

Functional components have no state. Also, their props are passed as the first parameter to a function.

See: [Function and Class Components](#)

Pure components

```
import React, {PureComponent} from 'react'

...
}
```

Performance-optimized version of `React.Component`. Doesn't rerender if props/state hasn't changed.

See: [Pure components](#)

Component API

```
this.forceUpdate()
```

```
this.setState({ ... })
this.setState(state => { ... })
```

```
this.state
this.props
```

These methods and properties are available for Component instances.

See: [Component API](#)

Lifecycle

Mounting

<code>constructor</code> (props)	Before rendering #
<code>componentWillMount()</code>	Don't use this #
<code>render()</code>	Render #
<code>componentDidMount()</code>	After rendering (DOM available) #
<code>componentWillUnmount()</code>	Before DOM removal #
<code>componentDidCatch()</code>	Catch errors (16+) #
Set initial the state on <code>constructor()</code> . Add DOM event handlers, timers (etc) on <code>componentDidMount()</code> , then remove them on <code>componentWillUnmount()</code> .	

Updating

<code>componentDidUpdate</code> (prevProps, prevState, snapshot)	Use <code>setState()</code> here, but remember to compare props
<code>shouldComponentUpdate</code> (newProps, newState)	Skips <code>render()</code> if returns false
<code>render()</code>	Render
<code>componentDidUpdate</code> (prevProps, prevState)	Operate on the DOM here
Called when parents change properties and <code>.setState()</code> . These are not called for initial renders. See: Component specs	

Hooks (New)

State Hook

```
import React, { useState } from 'react';

function Example() {
  // Declare a new state variable, which we'll call "count"

  return (
    <div>
      <p>You clicked {count} times</p>
      <button onClick={() => setCount(count + 1)}>
        Click me
      </button>
    </div>
  );
}
```

Hooks are a new addition in React 16.8.

See: [Hooks at a Glance](#)

Declaring multiple state variables

```
function ExampleWithManyStates() {
  // Declare multiple state variables!
  const [age, setAge] = useState(42);
  const [fruit, setFruit] = useState('banana');
  const [todos, setTodos] = useState([{ text: 'Learn Hooks' }]);
  // ...
}
```

Effect hook

```
import React, { useState, useEffect } from 'react';

function Example() {
  const [count, setCount] = useState(0);
```

```

}, [count]),

return (
  <div>
    <p>You clicked {count} times</p>
    <button onClick={() => setCount(count + 1)}>
      Click me
    </button>
  </div>
);
}

```

If you're familiar with React class lifecycle methods, you can think of `useEffect` Hook as `componentDidMount`, `componentDidUpdate`, and `componentWillUnmount` combined.

By default, React runs the effects after every render — including the first render.

Building your own hooks

Define `FriendStatus`

```

import React, { useState, useEffect } from 'react';

function FriendStatus(props) {
  const [isOnline, setIsOnline] = useState(null);

  useEffect(() => {
    function handleStatusChange(status) {
      setIsOnline(status.isOnline);
    }

    };
  }, [props.friend.id]);

  if (isOnline === null) {
    return 'Loading...';
  }

```

```
    return isOnline ? 'Online' : 'Offline';
  }
```

Effects may also optionally specify how to “clean up” after them by returning a function.

Use FriendStatus

```
function FriendStatus(props) {

  if (isOnline === null) {
    return 'Loading...';
  }
  return isOnline ? 'Online' : 'Offline';
}
```

See: [Building Your Own Hooks](#)

Hooks API Reference

Also see: [Hooks FAQ](#)

Basic Hooks

`useState(initialState)`

`useEffect(() => { ... })`

`useContext(MyContext)`

value returned from `React.createContext`

Full details: [Basic Hooks](#)

Additional Hooks

`useReducer(reducer, initialArg, init)`

`useCallback(() => { ... })`

`useMemo(() => { ... })`

`useRef(initialValue)`

`useImperativeHandle(ref, () => { ... })`

`useLayoutEffect`

identical to `useEffect`, but it fires synchronously after all DOM mutations

`useDebugValue(value)`

display a label for custom hooks in React DevTools

Full details: [Additional Hooks](#)

DOM nodes

References

```
class MyComponent extends Component {  
  render () {  
    return <div>  
  
    </div>  
  }  
  
  componentDidMount () {  
    this.setInputFocus(),  
  }  
}
```

Allows access to DOM nodes.

See: [Refs and the DOM](#)

DOM Events

```
class MyComponent extends Component {  
  render () {  
    <input type="text"  
      value={this.state.value}  
      onChange={this.handleChange} />  
  }  
  
  handleChange (event) {  
    this.setState({ value: event.target.value }, )  
  }  
}
```

Pass functions to attributes like onChange.

See: [Events](#)

Other features

Transferring props

```
<VideoPlayer src="video.mp4" />
```

```
class VideoPlayer extends Component {  
  render () {  
  
  }  
}
```

Propagates src="..." down to the sub-component.

See [Transferring props](#)

Top-level API

```
React.createClass({ ... })  
React.isValidElement(c)
```

```
ReactDOM.render(<Component />, domnode, [callback])  
ReactDOM.unmountComponentAtNode(domnode)
```

```
ReactDOMServer.renderToString(<Component />)  
ReactDOMServer.renderToStaticMarkup(<Component />)
```

There are more, but these are most common.

See: [React top-level API](#)

JSX patterns

Style shorthand

```
const style = { height: 10 }  
return <div style={style}></div>
```

```
return <div style={{ margin: 0, padding: 0 }}></div>
```

See: [Inline styles](#)

Inner HTML

```
function markdownify() { return "<p>...</p>"; }  
<div dangerouslySetInnerHTML={{__html: markdownify()}} />
```

See: [Dangerously set innerHTML](#)

Lists

```
class TodoList extends Component {  
  render () {  
    const { items } = this.props  
  
    return <ul>  
  
      {items.map(item => <li>{item}</li>)}  
  
    </ul>  
  }  
}
```

Always supply a key property.

Conditionals

```
<Fragment>  
  {showMyComponent  
    ? <MyComponent />  
    : <OtherComponent />}  
</Fragment>
```

Short-circuit evaluation

```
<Fragment>
  {showPopup && <Popup />}
  ...
</Fragment>
```

New features

Returning multiple elements

You can return multiple elements as arrays or fragments.

Arrays

```
render () {
  // Don't forget the keys!

  ...
}
```

Fragments

```
render () {
  // Fragments don't require keys!

  ...
}
```

See: [Fragments and strings](#)

Returning strings

```
render() {

}
```

You can return just a string.

See: [Fragments and strings](#)

Errors

```
class MyComponent extends Component {  
  ...  
  
}
```

Catch errors via `componentDidCatch`. (React 16+)

See: [Error handling in React 16](#)

Portals

```
render () {  
  
  
}
```

This renders `this.props.children` into any location in the DOM.

See: [Portals](#)

Hydration

```
const el = document.getElementById('app')
```

Use `ReactDOM.hydrate` instead of using `ReactDOM.render` if you're rendering over the output of [ReactDOMServer](#).

See: [Hydrate](#)

Property validation

PropTypes

```
import PropTypes from 'prop-types'
```

See: [Typechecking with PropTypes](#)

any	Anything
-----	----------

Basic

string

number

func	Function
------	----------

bool	True or false
------	---------------

Enum

oneOf(any)	Enum types
------------	------------

oneOfType(type array)	Union
-----------------------	-------

Array

array

arrayOf(...)

Object

object

objectOf(...)	Object with values of a certain type
---------------	--------------------------------------

instanceOf(...)	Instance of a class
-----------------	---------------------

shape(...)

Elements

element	React element
---------	---------------

node	DOM node
------	----------

Required

`(...).isRequired`

Required

Basic types

```
MyComponent.propTypes = {
  email:      PropTypes.string,
  seats:      PropTypes.number,
  callback:   PropTypes.func,
  isClosed:   PropTypes.bool,
  any:        PropTypes.any
}
```

Required types

```
MyCo.propTypes = {
  name:  PropTypes.string.isRequired
}
```

Elements

```
MyCo.propTypes = {
  // React element
  element: PropTypes.element,

  // num, string, element, or an array of those
  node: PropTypes.node
}
```

Enumerables (oneOf)

```
MyCo.propTypes = {
  direction: PropTypes.oneOf([
    'left', 'right'
  ])
}
```

Arrays and objects

```
MyCo.propTypes = {
  list: PropTypes.array,
  ages: PropTypes.arrayOf(PropTypes.number),
  user: PropTypes.object,
  user: PropTypes.objectOf(PropTypes.number),
}
```

```
message: PropTypes.instanceOf(Message)
}
```

```
MyCo.propTypes = {
  user: PropTypes.shape({
    name: PropTypes.string,
    age: PropTypes.number
  })
}
```

Use `.array[Of]`, `.object[Of]`, `.instanceOf`, `.shape`.

Custom validation

```
MyCo.propTypes = {
  customProp: (props, key, componentName) => {
    if (!/matchme/.test(props[key])) {
      return new Error('Validation failed!')
    }
  }
}
```
